

Feeding for energy and information

Erel Levine

Department of Physics and Center for Systems Biology, Harvard University, USA

Animals have evolved mechanisms for gathering information from the environment to make apt decisions. An important example is the regulation of feeding, where animals weigh nutritional value with the associated energetic costs and risks of pathogens and toxins. Here we will measure quantifiable feeding behaviors of the nematode *C. elegans*, observe unknown communications between tissues and among animals, and learn how these behaviors are designed to collect both energy and information.
