General motivation

The general and main motivation for research is to answer the question:

Why does the Universe exist?

More specific question for physicists:

How did our 'Material Universe' survive the cooling after the Big Bang?

Big Bang:
an equal amount of matter and antimatter was produced during the hot phase

During cooling and expansion
matter and antimatter annihilated 😐

**Most of the cosmic energy/matter budget is of an unknown form**

General motivation

Status of Standard Model in HEP:

- **The Standard Model has served us well for 50 years!**

- **Recent measurements indicates SM can't be the final answer.**

- **Six categories of problems have arisen in SM.**

Standard Model of Elementary Particles

General motivation

Dark Sector Candidates, Anomalies, and Search Techniques

- In SM: violation from weak interaction is not sufficient to create observed asymmetry

- Parameter space for BSM is running out at HEP

- several anomalies in experiments point to possible new physics, weakly coupled to familiar matter in the 1MeV - 1 GeV scale

  Ref: Marco Battaglieri, arXiv:1707.04591 [hep-ph]

Newest theoretical models prefer gauge bosons in MeV-GeV mass range as "…many of the more severe astrophysical and cosmological constraints that apply to lighter states are weakened or eliminated, while those from high energy colliders are often inapplicable" *(B. Batell , M. Pospelov, A. Ritz – 2009)*

How we can try to address SM problems experimentally?
- **Searching for new particles**
- **Studying violation of discrete symmetries**

Axions and Axion-Like-Particles

Connection between Standard and Dark Matter

New Physics connects to Standard Model particles through four portals:

Portal	Particles	Operator(s)
"Vector"	Dark photons	$-\frac{\epsilon}{2\cos\theta_W} B_{\mu\nu} F'^{\mu\nu}$
"Axion"	Pseudoscalars	$\frac{a}{f_a} F_{\mu\nu}\widetilde{F}^{\mu\nu}, \frac{a}{f_a} G_{i\mu\nu}\widetilde{G}_i^{\mu\nu}, \frac{\partial_\mu a}{f_a}\overline{\psi}\gamma^\mu\gamma^5\psi$
"Higgs"	Dark scalars	$(\mu S + \lambda S^2) H^\dagger H$
"Neutrino"	Sterile neutrinos	$y_N LHN$
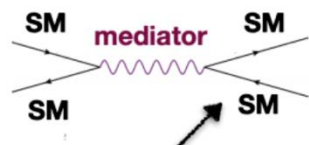

Invisible, non-SM

Dark Matter production

Producing stable particles that could be (all or part of) Dark Matter

SM → mediator → X
SM → mediator → X

Visible, SM

Production of portal-mediators that decay to SM particles

Systematically exploring the portal coupling to SM particles

SM → mediator → SM
SM → mediator → SM
visible

Mixed visible-invisible

Production of "rich" dark sectors

Testing the structure of the dark sector

SM → mediator $V_D^\pm$, A'^* → X, X, SM, SM

Light mesons studies:

η/η'

Stefania Gori, Mike Williams

Connection between Standard and Dark Matter

> **"*Light dark matter must be neutral under SM charges, otherwise it would have been discovered at previous colliders*"**
>
> <div align="right">[G. Krnjaic RF6 Meeting, 8/2020]</div>

- The only known particles with all-zero quantum numbers: $Q = I = J = S = B = L = 0$ are the **η/η' mesons** and the **Higgs boson (also the vacuum!)** -> <mark>**very rare**</mark>

- The **η** meson is a Goldstone boson (the η' meson is not!)

- The **η/η'** decays are flavor-conserving reactions

Experimental advantages:

- Hadronic production cross section is quite large (~ 0.1 barn) → much easier to produce than heavier mesons

- All its possible strong decays are forbidden in lowest order by P and CP invariance, G-parity conservation and isospin and charge symmetry invariance.

- EM decays are forbidden in lowest order by C invariance and angular momentum conservation Branching Ratio of processes from New Physics are enhanced compared to SM.

Axion-Like-Particles

**How to explain observed anomalies
in view of existing experimental constrains for QCD Axion ?**

Piophobic **QCD axion**

Must be short lived (~10^{-13} s) and decay predominantly to **e⁺ e⁻**

QCD Axion couples predominantly to the first generation of SM fermions (PQ charges vanish for second and third SM fermions)

The a - π⁰ mixing at the level of O(10^{-4})

Then in SM Lagrangian axionic phases are directly ascribed to quark masses

$$m_u \rightarrow m_u e^{i\gamma^5 q_{PQ}^u a/f_a},$$
$$m_d \rightarrow m_d e^{i\gamma^5 q_{PQ}^d a/f_a},$$
$$m_e \rightarrow m_e e^{i\gamma^5 q_{PQ}^e a/f_a},$$

$$\frac{m_u}{m_d} \simeq \frac{Q_d^{PQ}}{Q_u^{PQ}} = \frac{1}{2}$$

isovector

$$m_{u,d} \ll m_s \qquad \theta_{a\pi} \gg \theta_{a\eta}, \theta_{a\eta'}$$

isoscalar

$$\theta_{a\pi} \ll \theta_{a\eta}, \theta_{a\eta'}$$

Suppressed mixing-angle results in the isoscalar couplings of the axion

Ref: D. Alves et al., PHYS. REV. D 103, 055018 (2021)

Axion-Like-Particles

Hadronic decay channels of **η and η'** could be coupled to ALP's:

$$\eta \rightarrow \pi^+ \pi^- a (\rightarrow e^+ e^-)$$

"axio-hadronic decay"

Using Resonance Chiral Theory (RχT), the low-lying resonances should be included as degrees of freedom in the RχT Lagrangian
χPT predictions for decay rates significantly modified by inclusion of resonance exchange.

"…. O(10⁻²), is probably excluded or in tension with observations but O(10⁻⁴ - 10⁻³) likely remains experimentally allowed, and within the sensitivity."

D. Alves, S. Gonzàlez-Solís, JHEP 07 (2024) 264
$$BR(\eta \rightarrow \pi\pi a) \cdot 3 \cdot 10^{-8} - 4 \cdot 10^{-6}$$

Effects of pion-pion final-state interactions (FSI)

Axion-Like-Particles

η rest frame

> **Why previous measurements η(η') → π⁺ π⁻ e⁺ e⁻ did not see Axion signatures ?**

Experiments up to now focused on studies of CP invariance:
Year	Exp.	Events number	Asymmetry	BR ($\eta \to \pi^+ \pi^- e^+ e^-$)
2009	KLOE-2	1555 ± 52	$(-0.6 \pm 2.5_{stat} \pm 1.8_{sys}) \times 10^{-2}$	$(2.68 \pm 0.09_{stat} \pm 0.07_{syst}) \times 10^{-4}$
2016	WASA-at-COSY	251 ± 17	$(-1.1 \pm 6.6_{stat} \pm 0.2_{sys}) \times 10^{-2}$	$(2.7 \pm 0.2_{stat} \pm 0.2_{syst}) \times 10^{-4}$
2007	WASA-CELSIUS	$16.3 \pm 4.9 \pm 2.0$	-----	$(4.3 \pm 1.3_{stat} \pm 0.4_{syst}) \times 10^{-4}$

Rejected events
$m(e^+e^-) < 20$ MeV

BES III – Result for the η→ π⁺ π⁻ e⁺ e⁻ decay (also CP invariance studies):

R as a mas of axion
$$R^{\mathrm{UP}} = \frac{\mathcal{B}(\eta \to \pi^+ \pi^- a) \cdot \mathcal{B}(a \to e^+ e^-)}{\mathcal{B}(\eta \to \pi^+ \pi^- e^+ e^-)}$$

$$(3.0 - 53.0) \times 10^{-3}$$

# HADES - High Acceptance Di-Electron Spectrometer
February 2022 measurement:

- **proton – proton** collisions at energy of

  T = 4.5 GeV using LH_2 target

- **28 days** of measurement

- estimated total integrated luminosity

  ~ 6.1 [pb^{-1}]

- **START** – T0 reaction for ToF

- **RICH** – Cherenkov detector (di-electron e^+e^-)

- **MDC and STS** – track reconstruction

- **Magnet Coil** – generates magnetic field

- **ToF & RPC** – Time-of-Flight META detectors

- **ECAL** – electromagnetic calorimeter (photons)

- **Trigger logic based on InnerToF and Meta**

# Particle selection and identification

no RICH
RICH selected e⁺ e⁻
Following particles have to be selected: π^+ π^- e^+ e^-

- leptons selected by correlation windows (θ_{RICH} - θ_{MDC}) in RICH and MDC
- pions selected by cuts on beta vs momentum distribution
- additional cuts for leptons: **β > 0.9**

Event selection for the η → π⁺ π⁻ e⁺ e⁻ decay

- vertexReco z ∈ (-200 mm, 0)

- **π⁺ π⁻ e⁺ e⁻ missing mass vs inv. mass (graphical cut)**
Event selection for the η → π⁺ π⁻ e⁺ e⁻ decay

- **(e⁺e⁻)(π⁺π⁻) opening angle < 50° cut**

- **π⁺π⁻ invariant mass < 480 MeV cut**

- **(e⁺e⁻)(π⁺π⁻) opening angle in CM > 140°**
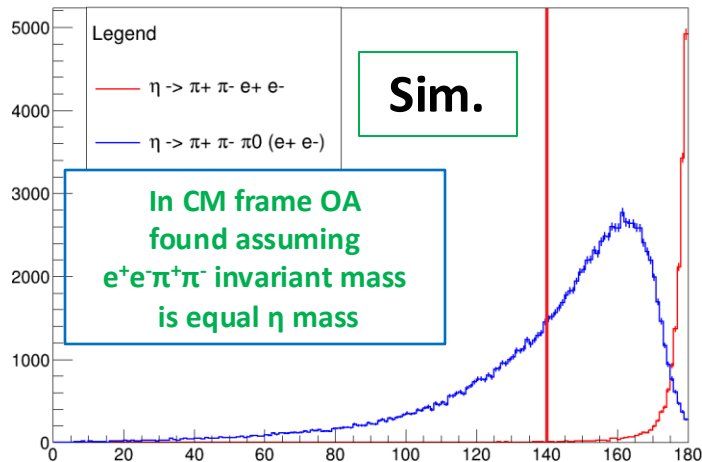

Event selection for the η → π⁺ π⁻ e⁺ e⁻ decay

- **all cuts were compared using e⁺e⁻π⁺π⁻ invariant mass**

- **Most of the multipion background was substracted**

- **reduction of 86.78% events in total range of e⁺e⁻π⁺π⁻ invariant mass distribution (data)**

- **reduction of 10.16% events in η signal range (simulations)**

The experimental invariant mass after the application of consecutive cuts.

Legend
- no cuts

Extraction of η → π⁺ π⁻ e⁺ e⁻ signal
| Estimated numer of signal events	**2758**
η peak mean (MeV)	548.40
η peak sigma (MeV)	32.59

Results

- Final distribution of e⁺e⁻ invariant mass after background subtraction
- Estimated total efficiency and acceptance factor: **1.1 · 10⁻³**

Upper limit for the number of event estimated based on W. A. Rolke method:

Ref. *Nuc. Instr. and Met. in Phys. A, 551, 2-3 (2012)*

$N^{UL}_{X17} = 255$ (CL=90%)

$BR_{\eta \to \pi^+\pi^- X17} < 2.58 \cdot 10^{-5}$

$BR^{theory}_{\eta \to \pi^+\pi^- a} < 4 \cdot 10^{-6}$

Conclusions

- *η/η' mesons are an interesting place to look for dark particles because probe coupling to light quarks and gluons.*

- *Preliminary estimation of upper limit for the Axion-Like-Particle in decay* $\eta \rightarrow \pi^+ \pi^- e^+ e^-$ is **BR < 2.58 · 10^{-5}** .

Further steps:

- **Studies of systematical effects.**

- **More detailed simulations of η decays and background using transport models SMASH/GiBUU.**

- **Application of Machine Learning techniques (MVA, BDT) to reduce background.**

Thank you for your attention!

Estimation of X17 contribution to signal region

Right peak (R)

$$\eta \to \pi^+ \pi^- e^+ e^-$$

$$\eta \to \pi^+ \pi^- \gamma$$

$$\eta \to \pi^+ \pi^- X17 \, (e^+ e^-)$$

Left peak (L)

$$\eta \to \pi^+ \pi^- \pi^0 \, (e^+ e^- \gamma)$$

$$\eta \to \pi^+ \pi^- \pi^0 \, (\gamma\gamma)$$

| Reaction	Contribution	Branching ratio (BR)
$\eta \to \pi^+ \pi^- e^+ e^-$	39.95%	$2.68 \cdot 10^{-4}$
$\eta \to \pi^+ \pi^- X17 \, (e^+ e^-)$	26.28%	$1 \cdot 10^{-4}$
$\eta \to \pi^+ \pi^- \gamma$	33.77%	$4.28 \cdot 10^{-2}$

Expected numer of X$_{17}$ in signal peak
$$N_{X17} = N_{ALL} \cdot f_{X17}$$
$$N_{X17} = 2758 \cdot 26.28\% = \mathbf{725}$$
General motivation – ATOMKI results (X_{17} boson)

The ATOMKI group observed an excess of e^+e^- pairs emitted at large relative angle in the nuclear reactions:

^{3}H(p, e^+e^-)^{4}He,

^{11}B(p, e^+e^-)^{12}C.

^{7}Li(p, e^+e^-)^{8}Be.

Expected ^{8}Be Transition — Fast-moving photon, Electron, Positron — Particle paths are close together

Hypothetical — Slow-moving X boson, Electron, Positron — Particle paths are at wide angle

Phys. Rev. Lett. **116**, 042501 -
